## PART 7

### BEAM LOAD TABLES – RECTANGULAR HSS

#### 1. Introduction

*CISC Steel Design Series Part 7 (SDS-7)* provides tables for selecting flexural members and estimating maximum beam reactions. The Beam Load Tables for rectangular Hollow Structural Sections (HSS) on the following pages list the total uniformly distributed factored loads (UDL) for beams in strong-axis bending. Two sets of tables are provided: one set based on CSA G40.21-350W steel ( $F_y = 350$  MPa) and another based on ASTM A500 Grade C ( $F_y = 345$  MPa). Two design examples are given to illustrate the use of the tables.

The tables may be used for simply-supported beams that are either laterally braced or unbraced. For all member sizes,  $L_u$ , the maximum unbraced length with which a beam will reach either  $M_r = \phi M_p$  or  $M_r = \phi M_y$  (depending on the class of section) is greater than its maximum tabulated span.

The tables may also be used to estimate loads for other loading conditions by means of the "Equivalent Tabular Load" for the particular loading condition. See the design example on page 4.

The Beam Load Tables (sometimes referred to as "book loads") are frequently used to obtain maximum reactions for the design of connections, when beam reactions are not provided on the structural design drawings.

#### 2. Factored Resistances

The uniformly distributed loads are based on factored moment resistances calculated in accordance with S16:19 Clause 13.5. To obtain the net supported load (factored), the beam factored dead load should be deducted from the total tabulated load.

For beams with very short spans, the loads may be limited by the shear capacity of the web (Clause 13.4.1.1) rather than by the bending capacity of the section. The tabulated beam loads also take into account the shear reduction factor due to combined shear and moment (Clause 14.6), given by:

$$2.20 - 1.60 \frac{M_f}{M_r}$$

The limit states of web yielding and web crippling are not included and should be checked in accordance with Clause 14.3.2.

The following properties and resistances are provided at the bottom of the tables:

- $S_x$  = Elastic section modulus with respect to the strong axis,  $10^3 \text{ mm}^3$
- $Z_x$  = Plastic section modulus with respect to the strong axis,  $10^3 \text{ mm}^3$
- $I_x$  = Moment of inertia with respect to the strong axis,  $10^6 \text{ mm}^4$
- $C_{rt}$  = Shear constant, ratio of vertical shear force to maximum shear stress for the strong bending axis,  $\text{mm}^2$
- $V_{r \max}$  = Maximum factored shear resistance ( $\phi A_w F_s$ ) calculated in accordance with S16:19 Clause 13.4.1.1. The unreduced shear resistance,  $V_r = \phi A_w F_s$ , applies to beams with  $F_s > 0.6 F_y$  when  $M_f/M_r \leq 0.75$ , and to all beams with  $F_s \leq 0.6 F_y$ .

$V_{r\ min}$  = Minimum factored shear resistance under combined shear and moment calculated in accordance with Clause 14.6.  $V_{r\ min} = 0.6 \phi A_w F_y$  for beams with  $F_s > 0.6 F_y$ , and  $V_{r\ min} = \phi A_w F_s$  for beams with  $F_s \leq 0.6 F_y$ . For beams with  $F_s > 0.6 F_y$  where  $M_f / M_r > 0.75$ ,  $V_{r\ max}$  is multiplied by the above-mentioned reduction factor, and the reduced shear resistance falls between the maximum and minimum values. Alternatively,  $V_{r\ min}$  may be used conservatively in all cases.

### 3. Vertical Deflections

The column headed "Approximate Deflection" lists the approximate theoretical mid-span deflection at an assumed bending stress level of 240 MPa, for beams of various spans designed to support the tabulated factored loads.

The listed deflections are based on the nominal depth of the beam, and are calculated using the formula:

$$\Delta = \frac{5 W L^3}{384 E I}$$

For  $E = 200\ 000$  MPa and an assumed bending stress of 240 MPa, this formula reduces to:

$$\Delta = \frac{250 \times 10^{-6} L^2}{d} \quad \text{where:}$$

$\Delta$  = deflection, mm

$W$  = total uniform load including the dead load of the beam, kN

$L$  = beam span, mm

$E$  = modulus of elasticity, MPa

$I$  = moment of inertia, mm<sup>4</sup>

$d$  = section depth, mm

More accurate deflections can be determined by multiplying the approximate deflection values listed by the ratio of actual bending stress to the assumed bending stress of 240 MPa. Also see *Deflection of Flexural Members* in Part 5 of the Handbook.

## Design Examples

### 1. Given:

Design a simply-supported beam spanning 6 m to carry a uniformly distributed load of 15 kN/m specified live load and 7 kN/m specified dead load. The dead load includes an assumed beam dead load of 0.5 kN/m. The live load deflection is limited to  $L/300$ . The beam frames into supporting members, and the beam is laterally supported. Use CSA G40.21-350W steel.

### Solution:

Factored load,  $w_f = (1.25 \times 7) + (1.50 \times 15) = 31.3$  kN/m

Total factored load,  $W_f = 31.3 \times 6 = 188$  kN

Factored moment,  $M_f = w_f L^2 / 8 = 31.3 \times 6^2 / 8 = 141$  kN·m

Factored end shear,  $V_f = W_f / 2 = 94.0$  kN

From the Beam Load Tables for CSA G40.21-350W, try a rectangular HSS305x152x6.4 section:

$$W_r (6\ 000) = 228 \text{ kN} > 188 \text{ kN}$$

The tabulated beam loads take into account the factored shear resistance,  $V_r$  (including the reduced resistance under combined shear and moment according to S16:19 Clause 14.6, if applicable).

When the beam is bearing on supports rather than framing into supporting members, it is necessary to check that the factored bearing resistance is greater than or equal to the factored end reaction.

Approximate deflection listed at an assumed stress of 240 MPa = 30 mm

$$\text{Stress at specified live load} = \frac{M_{Live}}{S_x} = \frac{w_{live}}{w_f} \times \frac{M_f}{S_x} = \frac{15}{31.3} \times \frac{141 \times 10^6}{440 \times 10^3} = 154 \text{ MPa}$$

Live load deflection =  $30 \times 154 / 240 = 19.3$  mm

$L / 300 = 6\ 000 / 300 = 20.0$  mm > 19.3 mm.

The HSS305x152x6.4 beam is adequate.

## 2. Given:

Design a simply-supported beam spanning 6 m to carry equal point loads of 45 kN specified live load and 21 kN specified dead load applied at the one-third points. An additional beam dead load of  $w_d = 0.7$  kN/m is assumed. The live load deflection is limited to  $L/300$ . The beam frames into supporting members, and the beam is laterally supported. Use ASTM A500 Grade C steel.

## Solution:

Factored load of each point load,  $P_f = (1.25 \times 21) + (1.50 \times 45) = 93.8$  kN

Referring to the *Beam Diagrams and Formulas* in Part 5 of the Handbook (loading condition 9), the equivalent tabular load is:

$$W_f = \frac{8P_f a}{L} + 1.25w_d L = \frac{8 \times 93.8}{3} + 1.25 \times 0.7 \times 6 = 255 \text{ kN}$$

where  $a$  is the point load spacing, or  $L/3$ .

From the Beam Load Tables for ASTM A500 Grade C, try a rectangular HSS305x203x7.9 section:

$$W_r (6\ 000) = 296 \text{ kN} > 255 \text{ kN}$$

For loading conditions other than uniformly distributed, the shear resistance should be checked, because the end shear may be significantly different from that corresponding to the equivalent tabular load ( $W_f/2$ ).

Factored end shear,  $V_f = P_f + 1.25 w_d L / 2 = 93.8 + 2.6 = 96.4 \text{ kN} < V_{r\ min} = 736 \text{ kN}$

A more detailed calculation would indicate whether a greater shear resistance could be used (S16:19 Clause 14.6), but  $V_{r\ min}$  is sufficient here.

When the beam is bearing on supports rather than framing into supporting members, it is necessary to check that the factored bearing resistance is greater than or equal to the factored end reaction.

Approximate deflection listed at an assumed stress of 240 MPa = 30 mm

Factored moment,  $M_f = w_f L^2 / 8 = W_f L / 8 = 255 \times 6 / 8 = 191 \text{ kN}\cdot\text{m}$

$$\text{Stress at specified live load} \approx \frac{M_{Live}}{S_x} = \frac{P_{live}}{P_f} \times \frac{M_f}{S_x} = \frac{45}{93.8} \times \frac{191 \times 10^6}{594 \times 10^3} = 154 \text{ MPa}$$

Live load deflection =  $30 \times 154 / 240 = 19.3 \text{ mm}$

$L / 300 = 6\ 000 / 300 = 20.0 \text{ mm} > 19.3 \text{ mm}$

The HSS305x203x7.9 beam is adequate.
